

ABSTRACT:

A necktie knot simulator closely resembling the shape of a necktie knot. Generally consisting of a one piece body with three properly dimensioned apertures, one at the upper right, one at the upper left, and one at the base provide both a means to thread a necktie through the necktie knot simulator and frictional resistance. The back side of the necktie knot simulator is predominately open to allow wearer access to the necktie while threading it through the invention. The front surface of the necktie knot simulator can easily be modified to include inlays, logos, patterns or even precious and semi-precious gemstones.
